eigenvalues of R a.) USE an orthogonal Matrix A to transform \underline{y} to \underline{z} : $\underline{z} = A\underline{y}$

$$\begin{bmatrix} y_{11} \\ y_{12} \\ \vdots \\ y_{1p} \end{bmatrix} \underline{z}_i = A\underline{y}_i = \begin{bmatrix} a_{11}y_{11} + a_{12}y_{12} + \dots + a_{1p}y_{1p} \\ a_{21}y_{11} + a_{22}y_{12} + \dots + a_{2p}y_{1p} \\ \vdots \\ a_{p1}y_{11} + a_{p2}y_{12} + \dots + a_{pp}y_{1p} \end{bmatrix} = \begin{bmatrix} z_{i1} \\ z_{i2} \\ \vdots \\ z_{ip} \end{bmatrix}$$

$$E^{-1}H$$

$$A = C' = \begin{pmatrix} \alpha'_1 \\ \alpha'_2 \\ \vdots \\ \alpha'_p \end{pmatrix}$$

 α'_j is the j th normalized eigenvector of S .principle components (\underline{z}) to find the linear combination of the variables in an observation vector that have maximum variance.

$$\underline{z}_1 = \alpha'_1 \underline{y} = a_{11}y_1 + a_{12}y_2 + \dots + a_{1p}y_p \rightarrow S^2_{z_1} = \lambda_1$$

$$\underline{z}_2 = \alpha'_2 \underline{y} = a_{21}y_1 + a_{22}y_2 + \dots + a_{2p}y_p \rightarrow S^2_{z_2} = \lambda_2$$

$$\vdots$$

$$\underline{z}_p = \alpha'_p \underline{y} = a_{p1}y_1 + a_{p2}y_2 + \dots + a_{pp}y_p \rightarrow S^2_{z_p} = \lambda_p$$

Eigenvalues are the variances of the principle components, the proportion of variance explained by the first k principle component is:

$$\text{proportion of Variance} = \frac{\lambda_1 + \lambda_2 + \dots + \lambda_k}{\sum_{i=1}^p \lambda_i}$$

$$\sum_{i=1}^6 \theta_i = 3.22553 + 1.65603 + 1.01631 + 0.04112 + 0.00092 + 0.00003 = 6$$

$$\frac{\theta_1}{\sum \theta_i} = \frac{3.22553}{6} = 0.53716$$

$$\frac{\theta_1 + \theta_2}{\sum \theta_i} = \frac{3.22553 + 1.65603}{6} = 0.8136$$

Thus, two principle components are necessary to explain 80% of the total sample variance of the standardized variables.

Question 2. Factor Analysis

a.) Completion

Orthogonal two-factor Model

$$\underline{y} = \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \\ y_5 \\ y_6 \end{pmatrix}$$

- i) $y_1 = \lambda_{11}f_1 + \lambda_{12}f_2 + \epsilon_1$
 $y_2 = \lambda_{21}f_1 + \lambda_{22}f_2 + \epsilon_2$
 $y_3 = \lambda_{31}f_1 + \lambda_{32}f_2 + \epsilon_3$
 $y_4 = \lambda_{41}f_1 + \lambda_{42}f_2 + \epsilon_4$
 $y_5 = \lambda_{51}f_1 + \lambda_{52}f_2 + \epsilon_5$
 $y_6 = \lambda_{61}f_1 + \lambda_{62}f_2 + \epsilon_6$

Assumptions of the factor model:

$$E(f_j) = 0 \text{ for } j=1, 2$$

$$y_i = \lambda_{i1}f_1 + \lambda_{i2}f_2 + \epsilon_i$$

$$\text{Var}(f_j) = 1 \text{ for } j=1, 2$$

$$\text{Cov}(f_i, f_k) = 0 \text{ for } i \neq k$$

$$E(\epsilon_i) = 0 \text{ for } i=1, 2, 3, 4, 5, 6$$

$$\text{Var}(\epsilon_i) = \psi_i \text{ for } i=1, 2, 3, 4, 5, 6$$

$$\text{Cov}(\epsilon_i, \epsilon_k) = 0 \text{ for } i \neq k$$

$$\text{Cov}(\epsilon_i, f_j) = 0 \forall i, j$$

ii) $\text{Var}(y_i) = \text{Var}(\lambda_{i1}f_1 + \lambda_{i2}f_2 + \epsilon_i)$

$$\text{Var}(ay) = a^2 \text{Var}(y)$$

$$= \text{Var}(\lambda_{i1}f_1) + \text{Var}(\lambda_{i2}f_2) + \text{Var}(\epsilon_i)$$

$$= \underline{\lambda_{i1}^2} \text{Var}(f_1) + \underline{\lambda_{i2}^2} \text{Var}(f_2) + \underline{\text{Var}(\epsilon_i)}$$

$$= \lambda_{i1}^2 + \lambda_{i2}^2 + \psi_i$$

$$\therefore \text{Var}(y_i) = \lambda_{i1}^2 + \lambda_{i2}^2 + \psi_i$$

iii) $\text{Cov}(y_i) = E[(y_i - \bar{y}_i)(y_j - \bar{y}_j)]$

$$= E[y_i \cdot y_j]$$

$$= E[(\lambda_{i1}f_1 + \lambda_{i2}f_2 + \lambda_{i3}f_3)(\lambda_{j1}f_1 + \lambda_{j2}f_2 + \lambda_{j3}f_3)]$$

$$= E[\lambda_{i1}^2 f_1^2 + \lambda_{i1}\lambda_{i2}f_1f_2 + \lambda_{i1}\lambda_{i3}f_1f_3 +$$

$$\lambda_{i2}\lambda_{i1}f_2f_1 + \lambda_{i2}^2 f_2^2 + \lambda_{i2}\lambda_{i3}f_2f_3 +$$

$$\lambda_{i3}\lambda_{i1}f_3f_1 + \lambda_{i3}\lambda_{i2}f_3f_2 + \lambda_{i3}^2 f_3^2]$$

$$= \lambda_{i1}^2 \text{Cov}(f_1, f_1) + \lambda_{i1}\lambda_{i2} \text{Cov}(f_1, f_2) + \lambda_{i1}\lambda_{i3} \text{Cov}(f_1, f_3) +$$

$$\lambda_{i3}\lambda_{i1} \text{Cov}(f_3, f_1) + \lambda_{i3}\lambda_{i2} \text{Cov}(f_3, f_2) + \lambda_{i3}^2 \text{Cov}(f_3, f_3)$$

$$= \lambda_{i1}^2 + \lambda_{i2}^2 + \lambda_{i3}^2$$

demonstrated by 3-factor model,
two-factor model somehow.

$$\therefore \text{Cov}(y_i) = \lambda_{i1}^2 + \lambda_{i2}^2$$

$$\boxed{\begin{aligned} \text{Cov}(f_i, f_j) &= 0 \text{ for } i \neq j \\ \text{Cov}(f_i) &= 1 \end{aligned}}$$

$$\text{IV) } \text{Cov}(Y_i, Y_j)$$

$$= E[(Y_i - \mu_i)(Y_j - \mu_j)]$$

$$= E[Y_i \cdot Y_j]$$

$$= E[(\lambda_{i1}f_1 + \lambda_{i2}f_2)(\lambda_{j1}f_1 + \lambda_{j2}f_2)]$$

$$= E[\lambda_{i1}\lambda_{j1}f_1f_1 + \lambda_{i1}\lambda_{j2}f_1f_2 + \lambda_{i2}f_2\lambda_{j1}f_1 + \lambda_{i2}\lambda_{j2}f_2f_2]$$

$$= \lambda_{i1}\lambda_{j1} \text{Cov}(f_1, f_1) + \lambda_{i1}\lambda_{j2} \cancel{\text{Cov}(f_1, f_2)} + \lambda_{i2}\lambda_{j1} \cancel{\text{Cov}(f_2, f_1)} + \lambda_{i2}\lambda_{j2} \text{Cov}(f_2, f_2)$$

$$= \lambda_{i1}\lambda_{j1} + \lambda_{i2}\lambda_{j2}$$

$$\therefore \text{Cov}(Y_1, Y_6) = \lambda_{11}\lambda_{61} + \lambda_{12}\lambda_{62}$$

There's no obvious improvement in interpretation of the factors after loading rotated.

The goal of rotation is to obtain a simple structure of loadings in which each variable loads highly on only one factor, with small loadings on all other factors. ✓

Value of 0.5 or 0.6 is used as threshold to assess significance.

In $\Lambda^* = \Lambda T$: the third row and sixth row have multiple large loadings

In $\Lambda^* = \Lambda Q$: the first, third, sixth rows have multiple large loadings, which mean that the variance of the corresponding y_i can not be explained mostly by 1 factor.

In $\hat{\Lambda}$: The pattern is loading matrix without rotation much better.

y_2 is explained by factor 3

y_2, y_3, y_4, y_5 are explained by factor 1

y_6 is explained by factor 2.

I really don't see any obvious advantages of estimated Loadings in a. than the one calculated in question 2.b.

Because All the four Loading matrix have similar pattern and each row have one large loading value. Thus, I would say that these Loading matrix have similar performance.
